- (57) **ABSTRACT**
A deviation in rotational angle caused between an adjustment gear and a sensor housing is compensated for with a profile of a cable winding groove of a pulley of an attitude control mechanism to accurately synchronize the inclination angle of a seat back and the rotational angle of the sensor housing with each other. Thus, it is possible to keep an inertial element support surface, which serves as a sensor reference surface, accurately horizontal even at any seat back inclination angle to improve the accuracy of an acceleration sensor.

SEATBELT DEVICE

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to a seatbelt device configured to protect an occupant in a vehicle, and, more particularly, to a seatbelt device in which a seatbelt retractor is incorporated into a seat back of a reclining seat.

2. Description of the Related Art

A seatbelt device mounted on a vehicle is configured to protect an occupant seated on a seat when the vehicle crashes, or the like, by restraining the occupant with a seatbelt drawn out of a seatbelt retractor. The seatbelt retractor includes an acceleration sensor configured to detect acceleration that is larger than a predetermined value and applied in a horizontal direction when the vehicle crashes, or the like, and a lock mechanism for the seatbelt configured to prevent the seatbelt from being drawn out when the lock mechanism is actuated. Examples of an inertial element for use in the acceleration sensor include a ball and a self-standing inertial element.

In the case where a seatbelt retractor having an acceleration sensor of this type is provided in a seat back of a reclining seat, acceleration may not be detected adequately because the attitude of the seatbelt retractor is varied in accordance with the reclining angle (inclination angle) of the seat back. Thus, there are known seatbelt devices provided with an acceleration sensor capable of adequately detecting acceleration irrespective of the reclining angle of the seat back (see Japanese Patent Application Laid-open No. 2000-79867, Japanese Patent Application Laid-open No. 2000-52921, and Japanese Patent Application Laid-open No. H11-326362, for example).

In the seatbelt devices described in Japanese Patent Application Laid-open No. 2000-79867, Japanese Patent Application Laid-open No. 2000-52921, and Japanese Patent Application Laid-open No. H11-326362, a cable advancing/retracting mechanism, configured to advance and retract a cable by a length corresponding to the inclination angle of a seat back, is disposed at a coupling portion where a seat back support arm provided to project from a seat cushion and a reclining rotary shaft are coupled to each other. A sensor reference line of an acceleration sensor is controlled by a cable extending between the cable advancing/retracting mechanism and a seatbelt retractor such that the sensor reference line is always directed in the vertical direction to enable adequate detection of acceleration when the seat back is tilted forward or rearward.

The attachment angle of the seatbelt retractor to the seat back in the vehicle width direction (the left-right direction of the vehicle) is different in accordance with the vehicle model, the vehicle seat specifications, or the like in order to ensure that the seatbelt is drawn out smoothly. In a seatbelt device described in Japanese Patent Application Laid-open No. H11-326362, the attitude of an acceleration sensor is adjustable to the vertical direction in correspondence with variations in attachment angle not only in the front-back direction of the vehicle but also in the vehicle width direction.

SUMMARY OF THE INVENTION

The seatbelt devices described in Japanese Patent Application Laid-open No. 2000-79867 and Japanese Patent Application Laid-open No. 2000-52921 support variations in reclining angle of the seat back, that is, variations in attitude

of the seatbelt retractor in the front-back direction of the vehicle, but do not support variations in attachment angle in the vehicle width direction.

In the seatbelt device described in Japanese Patent Application Laid-open No. 2002-2446, the rotational position of an inertial sensor is fixed by laser welding or joining to support variations in attachment angle in the vehicle width direction. However, Japanese Patent Application Laid-open No. 2002-2446 does not disclose a cable advancing/retracting mechanism at all. The rotational position of the inertial sensor is fixed at different angles in accordance with the seat specifications. Thus, a dedicated part matching the attachment angle of the seatbelt retractor is required for the attitude of the acceleration sensor to be always directed in the vertical direction. However, designing, manufacturing, and having in stock a large number of dedicated parts matching a large variety of specifications leads to a cost increase and is not favorable.

Examples of the cable advancing/retracting mechanism include a rack and pinion type in which a rack and a pinion are combined to convert rotation of the pinion, which is synchronized with tilting motion of the seat back, into advancing/retracting operation of a cable via the rack. The seatbelt device described in Japanese Patent Application Laid-open No. H11-326362 adopts a cable advancing/retracting mechanism of a direct type, in which a cable is directly wound around a cam member (which is referred to as a "slider" in Japanese Patent Application Laid-open No. H11-326362 and which is occasionally referred to as a "pulley"), and in which the length of the cable wound around the cam member is varied in accordance with relative rotation between the cam member and a casing member that is tiltable together with the seat back to advance and retract the cable.

Specifically, the direct-type cable advancing/retracting mechanism includes a casing member (which is referred to as a "case" in Japanese Patent Application Laid-open No. H11-326362) fixed to the seat back to be tiltable together with the seat back, a lever member (which is referred to as a "seating portion-side plate" in Japanese Patent Application Laid-open No. H11-326362) fixed to the seat cushion, and a cam member around which a terminal portion of the cable is wound and which is fixed at a fixed position by the lever member when the seat back is in a predetermined tilting range to rotate relative to the tiltable casing member. A terminal fixing portion of an exterior tube configured to slidably hold the cable is provided at a cable introduction portion of the casing member. A terminal portion of the cable drawn out of a terminal portion of the exterior tube and wound in a winding groove of the cam member is fixed to the cam member.

In order to linearly transfer the tilting angle of the seat back to the acceleration sensor via the cable, it is necessary to accommodate fluctuations in length of the cable through adjustment during assembly. Therefore, in the cable advancing/retracting mechanism discussed above, a cable length adjustment mechanism is provided at the terminal fixing portion of the exterior tube provided at the casing member. The cable length adjustment mechanism adjusts the length of the cable drawn out of the terminal portion of the exterior tube. That is, the length of a portion of the cable (inner cable), which is housed in the exterior tube, that is drawn out of the terminal of the exterior tube may be adjusted by changing the position of the terminal of the exterior tube fixed to the casing member through the cable length adjustment mechanism.

In the cable advancing/retracting mechanism of the seatbelt device according to the related art described in Japanese Patent Application Laid-open No. 2000-79867, the cable length is adjusted before the cam member, which actually detects the turning angle (that is, at the middle of the cable),

3

because the cable length adjustment mechanism is provided at the casing member. Thus, there may remain slight slack in the cable between the cable length adjustment mechanism and the terminal portion of the cable. This may accordingly degrade the accuracy in detecting the turning angle, and reduce the accuracy in controlling the attitude of the acceleration sensor to lower the detection accuracy of the acceleration sensor. Since the cable length adjustment mechanism is provided at the casing member, which is an exterior part, the compactness of the outer shape of the cable advancing/retracting mechanism may be accordingly degraded.

The present invention has been made in view of the foregoing issues, and therefore has an object to provide a seatbelt device capable of keeping a sensor reference surface accurately horizontal even at any seat back inclination angle to improve the accuracy of an acceleration sensor.

In one aspect, the present invention provides a seatbelt device with the configuration described below.

A seatbelt retractor attached to a seat back of a reclining seat and configured to wind up a seatbelt when necessary; and a cable advancing/retracting mechanism disposed at a coupling portion at which the seat back and a seat cushion of the reclining seat are coupled to each other and configured to detect an inclination angle of the seat back when the seat back is tilted in a front-back direction of a vehicle, the cable advancing/retracting mechanism including a cable configured to transmit the tilting angle to the seatbelt retractor and advance and retract in a longitudinal direction of the cable over a distance corresponding to the inclination angle of the seat back, the seatbelt retractor including: a retractor frame fixed to the seat back as inclined in a left-right direction of the vehicle with respect to a line extending in an up-down direction at a center of the seat back in the left-right direction; a spindle supported by the retractor frame and configured to wind up the seatbelt; an acceleration sensor attached to the retractor frame to detect acceleration in the front-back direction of the vehicle; a lock mechanism configured to lock draw-out operation for the seatbelt in accordance with the acceleration in the front-back direction of the vehicle detected by the acceleration sensor; and an attitude control mechanism configured to keep a sensor reference surface of the acceleration sensor horizontal, the acceleration sensor including: a sensor cover fixed to the retractor frame; an inertial element configured to be moved in the front-back direction of the vehicle when acceleration that is equal to or more than a predetermined value is applied in the front-back direction of the vehicle; a sensor housing supported on the sensor cover and having a swing axis extending along the left-right direction of the vehicle and an inertial element support surface on which the inertial element is placed; and an actuation member configured to actuate the lock mechanism to lock the draw-out operation in conjunction with movement of the inertial element in the front-back direction of the vehicle, and the attitude control mechanism including: a rotary member configured to be turned by an angle corresponding to a distance over which the cable is advanced or retracted by the cable advancing/retracting mechanism; and a rotation transfer mechanism configured to transfer rotation of the rotary member to the sensor housing to swing the sensor housing in the front-back direction of the vehicle, wherein a turning axis of the rotary member and the swing axis of the sensor housing intersect each other at a predetermined angle with respect to the left-right direction of the vehicle with the swing axis of the sensor housing arranged in a horizontal direction with respect to the left-right direction of the vehicle, the inertial element support surface of the sensor housing is kept horizontal by swing motion of the sensor housing in the

4

front-back direction of the vehicle even if the seat back is tilted in the front-back direction of the vehicle, a rotational track surface of the rotary member and a rotational track surface of the sensor housing are non-parallel with each other, and a compensation unit is provided between the cable advancing/retracting mechanism and the attitude control mechanism, the compensation unit being configured to compensate for a deviation in rotational angle caused by such non-parallelism between the two rotational track surfaces when the rotation transfer mechanism transmits rotation from the rotary member to the sensor housing.

In another aspect, the seatbelt device has an attitude control mechanism includes a pulley configured to convert advancing and retracting motion of the cable into rotational motion to transmit rotation to the rotary member, and a winding radius of the cable is set so as to be varied in accordance with a rotational angle of the pulley by forming a cable winding portion of the pulley in a spline curve shape, and the compensation unit is constituted by the cable winding portion of the pulley formed in the spline curve shape.

In a further aspect, the cable advancing/retracting mechanism includes a cam member configured to allow the cable to be wound and pulled out in accordance with rotation to advance and retract the cable over a distance corresponding to the inclination angle of the seat back, and a winding radius of the cable is set so as to be varied in accordance with a rotational angle of the cam member by forming a cable winding portion of the cam member in a spline curve shape, and the compensation unit is constituted by the cable winding portion of the cam member formed in the spline curve shape.

In an additional aspect, the rotation transfer mechanism includes a pin and a slit provided on the rotary member and in the sensor housing, respectively, and disposed at positions away from the swing axis and the turning axis in a radial direction to be engaged with each other.

In another aspect, the seatbelt retractor is attached to a seat back of a reclining seat and configured to wind up a seatbelt when necessary; and a cable advancing/retracting mechanism disposed at a coupling portion at which the seat back and a seat cushion of the reclining seat are coupled to each other and configured to detect an inclination angle of the seat back when the seat back is tilted in a front-back direction of a vehicle, the cable advancing/retracting mechanism including a cable configured to transmit the tilting angle to the seatbelt retractor and advance and retract in a longitudinal direction of the cable over a distance corresponding to the inclination angle of the seat back, the seatbelt retractor including: a retractor frame fixed to the seat back as inclined in a left-right direction of the vehicle with respect to a line extending in an up-down direction at a center of the seat back in the left-right direction; a spindle supported by the retractor frame and configured to wind up the seatbelt; an acceleration sensor attached to the retractor frame to detect acceleration in the front-back direction of the vehicle; a lock mechanism configured to lock draw-out operation for the seatbelt in accordance with the acceleration in the front-back direction of the vehicle detected by the acceleration sensor; and an attitude control mechanism configured to keep a sensor reference surface of the acceleration sensor horizontal, and the acceleration sensor including: a sensor cover fixed to the retractor frame; an inertial element configured to be moved in the front-back direction of the vehicle when acceleration that is equal to or more than a predetermined value is applied in the front-back direction of the vehicle; a sensor housing supported on the sensor cover and having a swing axis extending along the left-right direction of the vehicle and an inertial element support surface on which the inertial element is placed; and an

5

actuation member configured to actuate the lock mechanism to lock the draw-out operation in conjunction with movement of the inertial element in the front-back direction of the vehicle, in which the attitude control mechanism includes a pulley configured to convert advancing and retracting motion of the cable of the cable advancing/retracting mechanism into rotational motion, and a rotational track surface of the pulley and a rotational track surface of the sensor housing are non-parallel with each other, and a compensation unit is provided between the cable advancing/retracting mechanism and the attitude control mechanism, the compensation unit being configured to compensate for a deviation in rotational angle caused by such non-parallelism between the two rotational track surfaces when rotation is transmitted from the pulley to the sensor housing.

In yet a further aspect, a winding radius of the cable is set so as to be varied in accordance with a rotational angle of the pulley by forming a cable winding portion of the pulley in a spline curve shape, and the compensation unit is constituted by the cable winding portion of the pulley formed in the spline curve shape.

In still another aspect, the cable advancing/retracting mechanism includes a cam member configured to allow the cable to be wound and pulled out in accordance with rotation to advance and retract the cable over a distance corresponding to the inclination angle of the seat back, and a winding radius of the cable is set so as to be varied in accordance with a rotational angle of the cam member by forming a cable winding portion of the cam member in a spline curve shape, and the compensation unit is constituted by the cable winding portion of the cam member formed in the spline curve shape.

In yet another aspect, the attitude control mechanism further includes a rotary member configured to be turned by an angle corresponding to a distance over which the cable is advanced or retracted by the cable advancing/retracting mechanism in synchronization with rotation of the pulley, and a rotation transfer mechanism configured to transfer rotation of the rotary member to the sensor housing to swing the sensor housing in the front-back direction of the vehicle, the sensor cover is provided separately from the attitude control mechanism, and the sensor cover is formed such that a turning axis of the rotary member and the swing axis of the sensor housing intersect each other at a predetermined angle with respect to the left-right direction of the vehicle with the swing axis of the sensor housing arranged in a horizontal direction with respect to the left-right direction of the vehicle.

In an additional aspect, the rotation transfer mechanism includes a pin and a slit provided on the rotary member and in the sensor housing, respectively, and disposed at positions away from the swing axis and the turning axis in a radial direction to be engaged with each other.

In still a further aspect, the cable advancing/retracting mechanism includes a lever member fixed to the seat cushion, a casing member disposed coaxially with a center of turning motion of the seat back so as to be turnable with respect to the lever member, the casing member being fixed to the seat back to be turned as the seat back is tilted, and a cam member provided coaxially with the center of turning motion of the seat back so as to be turnable with respect to the lever member and the casing member, the cam member being hindered from moving by the lever member when the casing member is turned as the seat back is tilted while a tilting angle of the seat back is in a predetermined range, the casing member includes an exterior tube terminal fixing portion for fixation of a terminal portion of an exterior tube configured to slidably hold the cable, the cam member includes a cable winding groove which is formed along an outer peripheral surface of the cam

6

member and in which the cable drawn out of the terminal portion of the exterior tube is wound, and the cam member is provided with a cable length adjustment mechanism including a cable adjuster and a cable adjuster moving unit, the cable adjuster including a cable terminal fixing portion for fixation of the terminal portion of the cable wound in the cable winding groove and mounted so as to be linearly slidable at an outer peripheral portion of the cam member, and the cable adjuster moving unit being configured to slide the cable adjuster to adjust a length of the cable drawn out of the terminal portion of the exterior tube.

In a further aspect of the invention, the cable adjuster moving unit includes a screw receiving wall formed on the cam member, a screw insertion hole formed to penetrate the screw receiving wall, a screw hole formed in an end surface of the cable adjuster in a slide direction, and an adjustment screw screwed into the screw hole of the cable adjuster with a head portion received by the screw receiving wall and with a distal end side of a screw shaft portion inserted through the screw insertion hole, and the cable adjuster is displaced via the adjustment screw by rotating the adjustment screw.

In another aspect, the cable adjuster moving unit includes a spring configured to urge the cable adjuster in a direction of drawing the cable out of the terminal portion of the exterior tube.

In yet a further aspect, the lever member, the casing member, and the cam member are provided with respective positioning holes configured to penetrate the three members when the members are aligned with each other.

In still another aspect, the cable adjuster is mounted at the outer peripheral portion of the cam member so as to be slidable in a direction of a tangent to a circle centered about the center of turning motion of the seat back.

As used herein, the terms “up-down” and “up-down direction” indicate the direction from the center to the floor or the ceiling of the vehicle. The terms “left-right” and “left-right direction” indicate the vehicle width direction.

The terms “horizontal” and “horizontal direction” include the horizontal (horizontal direction), and may allow such a small error that may be caused during manufacture or that may still produce the effect of the present invention in designing a product.

The term “spline curve” includes curves other than spline curves, such as a curve drawn on the circumference of a circle obtained when a circle provided on a first plane is projected onto a second plane that is not parallel with the first plane from a location vertically above the second plane, for example.

For the phrase “inclination angle of the seat back in the front-back direction of the vehicle”, the detection range of the inclination angle of the seat back is set such that the inclination angle is detectable from a state in which the seat back stands upright to allow an occupant to be seated to a state in which the seat back is leaned toward the rear of the vehicle. However, the angle detection portion may be designed such that the inclination angle is detectable from a state in which the seat back is leaned forward to a state in which the seat back is leaned rearward throughout, and the detection range of the inclination angle of the seat back may be set as desired in accordance with a request from a user.

For the phrase “inclined in the left-right direction of the vehicle with respect to a line extending in the up-down direction at the center of the seat back in the left-right direction”, only inclination of $\pm 15^\circ$ in the left-right direction with respect to a line extending in the up-down direction is described in the

7

following embodiment. However, inclination of 0° to $\pm 45^\circ$ in the left-right direction may be set as long as designed reasonably.

For the phrase “a turning axis of the rotary member and the swing axis of the sensor housing intersect each other at a predetermined angle with respect to the left-right direction of the vehicle”, the predetermined angle is determined such that the swing axis of the sensor housing is arranged in the horizontal direction. Basically, the predetermined angle is determined in accordance with the inclination angle of the retractor attached to the seat back with respect to the left-right direction of the vehicle. That is, the predetermined angle is set in accordance with the attachment angle of the retractor.

In the seatbelt device according to the present invention, the rotational track surfaces of the rotary member or the pulley and the sensor housing are non-parallel with each other when rotation by an angle corresponding to the inclination angle of the seat back is transmitted from the rotary member or the pulley to the sensor housing. Because of such non-parallelism, the position of the contact point for power transfer is varied in the radial direction in accordance with the rotational angle position, and the contact point follows a non-circular (elliptical) track. Consequently, a deviation in rotational angle is caused between the rotary member and the sensor housing, or between the pulley and the sensor housing, and the inertial element support surface of the sensor housing may not be kept accurately horizontal with the inclination angle of the seat back and the rotational angle of the sensor housing not synchronized with each other.

With the seatbelt device according to the present invention, however, such a deviation in rotational angle is compensated for by the compensation unit provided between the cable advancing/retracting mechanism and the attitude control mechanism. Thus, the inclination angle of the seat back and the rotational angle of the sensor housing may be accurately synchronized with each other. Thus, it is possible to keep an inertial element support surface, which serves as a sensor reference surface, accurately horizontal even at any seat back inclination angle to improve the accuracy of an acceleration sensor.

The cable length adjustment mechanism is provided at the outer peripheral portion of the cam member which actually detects the tilting angle of the seat back, and adjusts the length of the cable drawn out of the terminal portion of the exterior tube by moving with the cable adjuster pulling the terminal portion of the cable. Thus, the length of the cable may be adjusted accurately such that no slack is caused in the cable. Thus, the accuracy in advancing and retracting the cable in accordance with the reclining angle of the seat back is enhanced to improve the performance of the acceleration sensor. A compact configuration is achieved with the cable adjuster disposed at the outer peripheral portion of the cam member.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1A is a side view of a reclining seat including a seatbelt device according to the present invention, FIG. 1B is a rear view of the reclining seat as a left seat, and FIG. 1C is a rear view of the reclining seat as a right seat;

FIG. 2A is a sectional view of a seatbelt retractor for the right seat attached as inclined leftward by a predetermined angle θ as seen from the front side of the vehicle in the first embodiment of the present invention, and FIG. 2B is a sectional view of a seatbelt retractor for the left seat attached as inclined rightward by the predetermined angle θ as seen from the front side of the vehicle;

FIG. 3 is an exploded perspective view of the seatbelt retractor;

FIG. 4 is an exploded perspective view of an acceleration sensor and an attitude control mechanism of the seatbelt retractor;

FIG. 5A is a perspective view illustrating the acceleration sensor and the attitude control mechanism in an assembled state, and FIG. 5B is a side view of the assembly;

FIG. 6 is a sectional view taken along the line VI-VI of FIG. 5B and illustrating the seatbelt retractor attached as inclined rightward by the predetermined angle θ ;

FIG. 7A is a perspective view illustrating the configuration of a sensor housing for use in the seatbelt retractor for the left seat, and FIG. 7B is a perspective view illustrating the configuration of a sensor housing for use in the seatbelt retractor for the right seat;

FIG. 8A is a side view illustrating the seatbelt retractor attached as inclined in the vehicle width direction (rightward), FIG. 8B illustrates the moving track of a pin of an adjustment gear (rotary member) of the attitude control mechanism as seen from a direction perpendicular to the rotational track surface (a surface inclined with respect to a vertical surface) of the adjustment gear, FIG. 8C illustrates the moving track of the pin of the adjustment gear as seen from a direction (horizontal direction) perpendicular to the rotational track surface (vertical surface) of the sensor housing, FIG. 8D illustrates the moving track of a slit as seen from a direction (horizontal direction) perpendicular to the rotational track surface (vertical surface) of the sensor housing, and FIG. 8E is a view in which the moving tracks of FIGS. 8C and 8D are synthesized;

FIG. 9A is a perspective view of a pulley of the attitude control mechanism for use in the seatbelt retractor for the left seat, FIG. 9B is an end view of the pulley, FIG. 9C is a cross-sectional view taken along the line IXc-IXc of FIG. 9B, FIG. 9D is a perspective view of a pulley of the attitude control mechanism for use in the seatbelt retractor for the right seat, FIG. 9E is an end view of the pulley, and FIG. 9F is a cross-sectional view taken along the line IXf-IXf of FIG. 9E;

FIG. 10 illustrates variations in radius of a cable winding groove of the pulley from the center of rotation [radius r of a cable winding groove 73b of FIGS. 9C and 9F];

FIG. 11 is an exploded perspective view illustrating the configuration of a cable advancing/retracting mechanism;

FIG. 12 is a front view illustrating the internal configuration of the cable advancing/retracting mechanism;

FIG. 13A is a side view illustrating the seatbelt retractor and the cable advancing/retracting mechanism with a seat back leaned rearward by 15° in a standard state, and FIG. 13B is a front view illustrating the internal state of the cable advancing/retracting mechanism with the seat back leaned rearward by 15° ;

FIG. 14A is a side view illustrating the seatbelt retractor and the cable advancing/retracting mechanism with the seat back leaned rearward by 95° , and FIG. 14B is a front view illustrating the internal state of the cable advancing/retracting mechanism with the seat back leaned rearward by 95° ;

FIG. 15A is a side view illustrating the seatbelt retractor and the cable advancing/retracting mechanism with the seat back leaned forward by 75° , and FIG. 15B is a front view illustrating the internal state of the cable advancing/retracting mechanism with the seat back leaned forward by 75° ; and

FIG. 16 illustrates a method of adjusting the length of a cable in the cable advancing/retracting mechanism.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

A seatbelt device according to an embodiment of the present invention will be described in detail below with reference to the drawings.

As illustrated in FIGS. 1A to 1C, a seatbelt device 10 according to the embodiment includes a seatbelt retractor 11 and a cable advancing/retracting mechanism 100. The seatbelt retractor 11 is attached to a seat back 16 of a reclining seat 15, and capable of winding up a seatbelt 19. The cable advancing/retracting mechanism 100 is disposed at a coupling portion 18 at which the seat back 16 and a seat cushion 17 of the reclining seat 15 are turnably coupled to each other. The cable advancing/retracting mechanism 100 transmits tilting operation of the seat back 16 to the seatbelt retractor 11 via a cable 13a (which is also referred to as an "inner cable") by advancing and retracting the inner cable 13a by a length corresponding to the tilting angle of the seat back 16. The seatbelt device 10 has a function of restraining an occupant in a vehicle with respect to the reclining seat 15 when the vehicle crashes.

The inner cable 13a is covered by an exterior tube 13b (see FIG. 3) to be discussed later to constitute a cable unit 13. Terminal members 13d at both ends of the exterior tube 13b are fixed to the seatbelt retractor 11 and a casing member 120 (see FIG. 11) of the cable advancing/retracting mechanism 100, which is discussed later. This allows the inner cable 13a housed inside the exterior tube 13b to smoothly slide with respect to the exterior tube 13b in the direction of extension to advance and retract without slack in the inner cable 13a.

The seatbelt retractor 11 is tiltable to any angle in the front-back direction of the vehicle in accordance with the reclining angle of the seat back 16. In the vehicle width direction (left-right direction of the vehicle), the seatbelt retractor 11 is attached at a predetermined angle θ that is different in accordance with the vehicle model or the seat specifications in order to enable the seatbelt 19 to be smoothly paid out from the seatbelt retractor 11. Herein, the seatbelt retractor 11 is attached to the seat back 16 in a reference attachment attitude, in which the seatbelt retractor 11 is inclined toward the rear of the vehicle by approximately 15° (leaned rearward by 15°) and inclined by a predetermined angle θ ($=15^\circ$) in the vehicle width direction. That is, for a left seat, the seatbelt retractor 11 is attached as inclined leftward by the predetermined angle θ ($=15^\circ$) as seen from the rear side as illustrated in FIG. 1B, and for a right seat, attached as inclined rightward by the predetermined angle θ ($=15^\circ$) as seen from the rear side as illustrated in FIG. 1C.

As illustrated in FIGS. 2 and 3, the seatbelt retractor 11 includes a retractor frame 21 fixed to the seat back 16 as inclined in the left-right direction of the vehicle with respect to a line extending in the up-down direction at the center of the seat back 16 in the left-right direction. A spindle 22 configured to wind up the seatbelt 19 is rotatably supported on the retractor frame 21.

A retractor spring 23 is coupled on the one end side of the spindle 22 in the axial direction. The retractor spring 23 urges the spindle 22 to rotate in the direction of winding up the seatbelt 19. The retractor spring 23 is housed in a cover 23a.

A steering wheel 25, an acceleration sensor 30, and an attitude control mechanism 70 are provided on the other end side of the spindle 22 in the axial direction. The steering wheel 25 is a constituent element of a lock mechanism 24 configured to lock draw-out operation for the seatbelt 19. The acceleration sensor 30 detects acceleration in the front-back direction applied to the vehicle, and actuates the lock mechanism 24 in accordance with the detected acceleration.

The attitude control mechanism 70 keeps a sensor reference surface (inertial element support surface 33 to be discussed later) generally horizontal irrespective of the tilting angle of the seat back 16.

The steering wheel 25 is joined so as to rotate together with the spindle 22, and has a plurality of engagement lugs 25a arranged on the outer peripheral surface at predetermined intervals in the circumferential direction to engage with an upper lug portion 36b of an actuation member (first sensor lever 36) to be discussed later. The steering wheel 25 is housed inside a steering wheel cover 27. The entire side surface of the seatbelt retractor 11 on the other end side including the acceleration sensor 30 is covered by a retractor cover 29.

As illustrated in FIGS. 3 and 4, the acceleration sensor 30 includes a sensor cover 31, a sensor housing 32, an iron ball 35, and a second sensor lever 37. The sensor cover 31 is fixed to the outside surface of the retractor frame 21 so as to be tiltable in the front-back direction of the vehicle together with the seat back 16. The sensor housing 32 is supported so as to be swingable in the front-back direction of the vehicle with respect to the sensor cover 31 about a swing axis L1 (see FIG. 6) extending along the left-right direction of the vehicle. The sensor housing 32 is turned in the front-back direction of the vehicle with respect to the sensor cover 31 by the attitude control mechanism 70 when the seat back 16 is tilted to keep the inertial element support surface 33, which serves as the sensor reference surface, generally horizontal in the front-back direction of the vehicle. The ball 35 serves as an inertial element supported on the inertial element support surface 33 of the sensor housing 32 to be displaced from the neutral position when acceleration in the front-back direction of the vehicle that is a predetermined value or more is applied. The second sensor lever 37 serves as an actuation member configured to actuate the lock mechanism 24 to lock the draw-out operation in conjunction with displacement of the ball 35 in the front-back direction of the vehicle.

Specifically, as also illustrated in FIG. 6, a pair of boss portions 32a and 32b provided to project from the outside surface of the sensor housing 32 are fitted in a pair of support holes 31a and 31b of the sensor cover 31, respectively, to constitute the swing axis L1. This makes the sensor housing 32 swingable in the front-back direction of the vehicle about the swing axis L1. As illustrated in FIG. 4, a pair of turning projections 37a and 37b of the second sensor lever 37 are fitted in lever support holes 32e and 32f formed in a pair of brackets 32c and 32d of the sensor housing 32, respectively. Thus, the second sensor lever 37 is supported so as to be turnable in the front-back direction of the vehicle with respect to the sensor housing 32.

The sensor housing 32 has the inertial element support surface 33, which is a bowl-shaped downwardly concave surface, as the upper inner bottom surface. The ball 35 is placed on the inertial element support surface 33. The ball 35, which serves as an inertial element, is displaced from the neutral position upon receiving acceleration in the front-back direction of the vehicle that is a predetermined value or more to sense acceleration applied to the vehicle (that is, the seatbelt retractor 11). When the inertial element support surface 33 discussed earlier is generally horizontal, it is meant that the reference surface of the inertial element support surface 33 (for example, the upper surface of the inertial element support surface 33) is generally horizontal.

As illustrated in FIG. 3, the first sensor lever 36 is formed in a generally Y shape. The base end portion of the first sensor lever 36 has a boss portion 36a provided with a fitting hole.

11

The distal end portion of the first sensor lever **36** has the upper lug portion **36b** in abutment with the steering wheel **25** and a lower lug portion **36c** in abutment with the second sensor lever **37**. The first sensor lever **36** is disposed below the steering wheel **25**. The fitting hole of the boss portion **36a** is turnably fitted with a support shaft (not illustrated) fixed to the retractor frame **21**. When the first sensor lever **36** is turned upward about the boss portion **36a** having the fitting hole, the upper lug portion **36b** is engaged with the engagement lugs **25a** of the steering wheel **25** to restrict rotation of the steering wheel **25**. Thus, the steering wheel **25** and the first sensor lever **36** constitute the lock mechanism **24**.

As illustrated in FIGS. **3** and **4**, the second sensor lever **37** includes the turning projections **37a** and **37b** formed at the base end portion, a cup portion **37c** formed on the distal end side to cover the upper surface of the ball **35**, and a rib **37d** formed on the upper surface of the cup portion **37c**. The turning projections **37a** and **37b** are turnably fitted in the lever support holes **32e** and **32f** of the sensor housing **32**, respectively. The cup portion **37c** of the second sensor lever **37** contacts the upper side of the ball **35**. The lower lug portion **36c** of the first sensor lever **36** abuts against the upper surface of the rib **37d**. When the ball **35** is displaced from the neutral position by acceleration, the second sensor lever **37** is turned upward to push the first sensor lever **36** upward via the lower lug portion **36c**, which engages the upper lug portion **36b** with the engagement lugs **25a** of the steering wheel **25** to lock the steering wheel **25**. The turning axes of the first sensor lever **36** and the second sensor lever **37** are positioned in directions opposite to each other from the center of the ball **35** so as to be turned in directions opposite to each other when the ball **35** is displaced.

As illustrated in FIGS. **3**, **4**, and **6**, the attitude control mechanism **70** which controls the attitude of the sensor housing **32** in the front-back direction is composed of a first pulley case **71**, a second pulley case **72**, a pulley **73**, an adjustment gear **74**, a torsion spring **75**, and a rotation transfer mechanism **76**. The first pulley case **71** and the second pulley case **72** are disposed inside side plates of the retractor frame **21**. The pulley **73** is housed in an internal space formed by combining the first pulley case **71** and the second pulley case **72** with each other. The torsion spring **75** urges the pulley **73** to rotate. The rotation transfer mechanism **76** transfers rotation of the adjustment gear **74** to the sensor housing **32** of the acceleration sensor **30**.

The pulley **73** is supported by the first pulley case **71** and the second pulley case **72** so as to be rotatable about a support shaft **71c** provided at the first pulley case **71**. The pulley **73** converts advancing and retracting motion of the inner cable **13a** caused by the cable advancing/retracting mechanism **100** into rotational motion to rotate in the same direction as the tilting direction of the seat back **16** by an angle corresponding to the advancing and retracting motion of the inner cable **13a**. A cable winding groove **73b** configured to receive the inner cable **13a** is provided in the outer peripheral surface of the pulley **73**. The one end portion (upper end portion) of the inner cable **13a** is fixed to the pulley **73** via an end block **13c**. The inner cable **13a** is slidably inserted in the exterior tube **13b**. The terminal member **13d** attached to one end of the exterior tube **13b** is fixed to the first pulley case **71** and the second pulley case **72**.

The torsion spring **75** (see FIG. **3**) urges the pulley **73** to rotate in the direction of winding up the inner cable **13a**. The adjustment gear **74** is a rotary member meshed with a gear **73a** formed at a side portion of the pulley **73** to synchronously rotate by the same rotational angle in the direction opposite to the tilting direction of the seat back **16**. As illustrated in FIG.

12

6, the adjustment gear **74** is supported so as to be turnable about a turning axis L2 with one shaft projection **74a** fitted in a support hole **71a** formed in the first pulley case **71** and with the other shaft projection **74b** having a spherical distal end fitted in a spherical hole **32g** formed in an end surface of the boss portion **32b** of the sensor housing **32** through a window **71b** (see FIG. **4**) of the first pulley case **71**. In this case, with the spherical hole **32g** and the spherical shaft projection **74b** fitted with each other, the turning axis L2 of the adjustment gear **74** and the swing axis L1 of the sensor housing **32** intersect each other at one point at the center of the shaft projection **74b** even if the two axes are in any angular relationship. That is, the turning axis L2 and the swing axis L1 of the sensor housing **32** are configured to intersect each other at one point with the turning axis L2 inclined with respect to the swing axis L1 by a certain angle both in the case where the two axes are on an identical line and in the case where the two axes are inclined with respect to each other.

The rotation transfer mechanism **76** is configured to swing the sensor housing **32** by transferring rotation of the adjustment gear **74** to the sensor housing **32** both in the case where the turning axis L2 of the adjustment gear **74** and the swing axis L1 of the sensor housing **32** are on an identical line and in the case where the two axes are inclined with respect to each other. Consequently, the rotation transfer mechanism **76** causes a sensor reference line S1 of the acceleration sensor **30** (a line that is perpendicular to the sensor reference surface which passes through the center point of the ball **35** in the neutral position) to be oriented in the vertical direction in the front-back direction of the vehicle to keep the inertial element support surface **33**, which is perpendicular to the sensor reference line S1 and serves as the sensor reference surface, generally horizontal. Therefore, the rotation transfer mechanism **76** in the embodiment is constituted by a combination of a pin **74c** and a slit **32h** formed on the adjustment gear **74** and in the sensor housing **32**, respectively, and disposed at positions away from the swing axis L1 and the turning axis L2 in the radial direction to be engaged with each other.

Although the pin **74c** is formed on the adjustment gear **74** and the slit **32h** is formed in the sensor housing **32** herein, the pin may be formed on the sensor housing **32** and the slit may be formed in the adjustment gear **74**. The slit **32h** is formed in an arm **32i** provided to project downward from a side portion of the sensor housing **32**. It is necessary that the arm **32i** should allow the slit **32h** and the pin **74c** to be reliably engaged with each other and not interfere with other portions. Therefore, the shape of the arm **32i** is slightly different between a sensor housing **32L** (**32**) for use in the seatbelt retractor for the left seat illustrated in FIG. **7A** and a sensor housing **32R** (**32**) for use in the seatbelt retractor for the right seat illustrated in FIG. **7B**.

The seatbelt retractor **11** configured as described above is attached to the seat back **16** in a reference attachment attitude that is different in accordance with the vehicle model or the seat specifications. For example, the seatbelt retractor **11** is attached as inclined toward the rear of the vehicle by approximately 15° and inclined by $\theta=15^\circ$ in the vehicle width direction (left-right direction). The seatbelt retractor **11** is attached in different inclination directions and at different angles in the vehicle width direction in accordance with the vehicle type or the seat specifications in order to enable the seatbelt **19** to be smoothly drawn out by matching the inclination of the spindle **22** in the vehicle width direction with the direction in which the seatbelt **19** is drawn out.

Thus, there are two attachment attitudes. In one of the two attachment attitudes, as illustrated in FIG. **6**, the retractor frame **21** is attached as inclined rightward by a predetermined

13

angle θ ($=15^\circ$) so that the rotational track surface of the pulley 73 and the adjustment gear 74 of the attitude control mechanism 70 is inclined rightward with respect to a vertical plane by the predetermined angle θ . Conversely, in the other attachment attitude, although not illustrated, the retractor frame 21 is attached as inclined leftward by the predetermined angle θ so that the rotational track surface of the pulley 73 and the adjustment gear 74 of the attitude control mechanism 70 is inclined leftward with respect to a vertical plane by the predetermined angle θ .

Because of such an attachment attitude, the embodiment is made on the premise that the turning axis L2 of the adjustment gear 74 is inclined with respect to a horizontal direction extending along the left-right direction of the vehicle by the predetermined angle θ . Different sensor covers 31 for the left and right seats are prepared so that the sensor reference line S1 of the acceleration sensor 30 is oriented in the vertical direction with the swing axis L1 of the sensor housing 32 of the acceleration sensor 30 kept generally horizontal even in the case where the turning axis L2 of the adjustment gear 74 is inclined with respect to the horizontal. Therefore, the turning axis L2 of the adjustment gear 74 which is inclined with respect to the horizontal and the swing axis L1 of the sensor housing 32 which is kept horizontal are not on an identical line, and the predetermined angle θ is made between the two axes.

Since the two axes (the swing axis L1 and the turning axis L2) are not on an identical line, the turning axis L2 of the adjustment gear 74 and the swing axis L1 of the sensor housing 32 are separate from each other and arranged to intersect each other at one point with the predetermined angle θ made between the two axes as discussed above. Then, the pin 74c and the slit 32h discussed earlier are combined with each other to constitute the rotation transfer mechanism 76.

The attachment angle of the retractor frame 21 may be set to any angle including $\theta=0^\circ$. The swing axis L1 of the sensor housing 32 may be always kept generally horizontal by attaching the acceleration sensor 30 to the retractor frame 21 using a dedicated sensor cover 31 prepared for each set attachment angle. In this event, rotation of the adjustment gear 74 may be naturally transmitted to the sensor housing 32 through the combination of the pin 74c and the slit 32h both in the case where the swing axis L1 of the sensor housing 32 and the turning axis L2 of the adjustment gear 74 are on an identical line and in the case where the two axes intersect each other as inclined with respect to each other (that is, both in the case where the rotational track surface of the adjustment gear 74 and the rotational track surface of the sensor housing 32 are parallel with each other and in the case where the two rotational track surfaces are non-parallel with each other).

Herein, it is necessary that the inclination angle (reclining angle) of the seat back 16 and the rotational angle of the sensor housing 32 (rotational angle in the direction opposite to the tilting angle of the seat back 16) should be accurately synchronized with each other. If the rotational angle of the seat back 16 and the rotational angle of the sensor housing 32 are not accurately synchronized with each other, the inertial element support surface 33 may not be kept accurately horizontal, which may not allow the acceleration sensor 30 to react precisely.

If the rotational track surface of the pulley 73 and the adjustment gear 74 and the rotational track surface of the sensor housing 32 are non-parallel with each other in the case where rotation is transmitted from the adjustment gear 74 to the sensor housing 32 through the slit 32h and the pin 74c as in the configuration described above, a deviation in rotational

14

angle due to such non-parallelism may be caused between the adjustment gear 74 and the sensor housing 32.

That is, in the case where the rotational track surfaces of the adjustment gear 74 and the sensor housing 32 are parallel with each other and the two axes (the turning axis L2 and the swing axis L1) are on an identical line, for example, the position of the contact point for power transfer between the pin 74c and the slit 32h is constant and not varied when the adjustment gear 74 and the sensor housing 32 rotate, and thus the contact point follows a perfect circle track. In the case where the rotational track surfaces of the adjustment gear 74 and the sensor housing 32 are non-parallel with each other, however, the position of the contact point is varied in the radial direction in accordance with the rotational angle, and therefore the contact point follows a non-circular (elliptical) rotational track.

A detailed description will be made below with reference to FIG. 8. A rotational track K1 of the slit 32h of the sensor housing 32 is a perfect circle as seen from a horizontal direction that is perpendicular to the rotational track surface (vertical surface) of the sensor housing 32 as illustrated in FIG. 8D. However, a rotational track K2 of the pin 74c of the adjustment gear 74 is a perfect circle as seen from a horizontal direction that is perpendicular to the rotational track surface (vertical surface) of the adjustment gear 74 as illustrated in FIG. 8B, but is an ellipse as seen from a horizontal direction that is perpendicular to the rotational track surface (vertical surface) of the sensor housing 32 as illustrated in FIG. 8C.

Therefore, the position of the contact point is varied in the radial direction in accordance with the rotational angle, and the contact point follows a non-circular track (which matches the elliptical track of the pin 74c) rather than a perfect circle track as illustrated in FIG. 8E. Consequently, a deviation in rotational angle is caused between the adjustment gear 74 and the sensor housing 32. For example, when the adjustment gear 74 is turned by 60° , the sensor housing 32 may be turned by 58° or 62° . Then, the inclination angle of the seat back 16 and the rotational angle of the sensor housing 32 are not synchronized with each other, and the inertial element support surface 33 of the sensor housing 32 may not be kept precisely horizontal.

Also in the case where the inclination direction of the attitude control mechanism 70 is opposite to that in FIG. 8A, the position of the contact point between the pin 74c and the slit 32h varied in the radial direction in accordance with the rotational angle, and the contact point follows an elliptical track. It should be noted, however, that the shape of the ellipse is different in accordance with differences in inclination direction of the attitude control mechanism 70.

Thus, a compensation unit configured to compensate for such a deviation in rotational angle is provided between the cable advancing/retracting mechanism 100 and the attitude control mechanism 70. The compensation unit transmits the inclination angle of the seat back 16 to the sensor housing 32 while correcting the inclination angle in accordance with the expected deviation in rotational angle. Consequently, the sensor housing 32 is turned with the deviation in rotational angle compensated for, which allows the sensor housing 32 to be turned substantially in synchronization with the inclination angle of the seat back 16.

Specifically, the compensation unit is provided at the pulley 73 of the attitude control mechanism 70 because advancing and retracting motion of the inner cable 13a extending from the cable advancing/retracting mechanism 100 precisely reflects the inclination angle of the seat back 16. That is, the attitude control mechanism 70 is provided with the pulley 73 which converts advancing and retracting motion of

15

the inner cable **13a** into rotational motion to transmit rotation to the adjustment gear **74**, and the path of the cable winding groove **73b** of the pulley **73** in the circumferential direction is formed in a non-perfect circle spline curve shape so that a radius r of the cable winding groove **73b** is varied in accordance with the rotational angle of the pulley **73**. That is, the compensation unit is constituted by the cable winding groove **73b** of the pulley **73** formed in a spline curve shape with a variable radius.

The profile (spline curve) of the cable winding groove **73b** is set on the basis of data on the deviation in rotational angle between the adjustment gear **74** and the sensor housing **32** obtained through calculation or actual measurement. FIGS. **9A** to **9C** illustrate the configuration of a pulley (which is referred to as an "L15° pulley" for convenience) for use in the seatbelt retractor for the left seat. FIGS. **9D** to **9F** illustrate the configuration of a pulley (which is referred to as an "R15° pulley" for convenience) for use in the seatbelt retractor for the right seat. FIG. **10** illustrates the profiles (variations in radius r from the center of rotation) of the cable winding grooves **73b** of the L15° pulley **73L** and the R15° pulley **73R** compared with that of a perfect circle pulley.

The radius r of the cable winding groove **73b** of both the pulleys **73L** and **73R** is determined to have a profile that allows compensation for the deviation in rotational angle between the adjustment gear **74** and the sensor housing **32**. Thus, the inclination angle of the seat back **16** and the rotational angle of the sensor housing **32** may be accurately synchronized with each other by incorporating the pulley **73L** or **73R** in the attitude control mechanism **70**. This allows the inertial element support surface **33**, which serves as the sensor reference surface, to be kept accurately horizontal even at any seat back inclination angle to improve the accuracy of the acceleration sensor **30**.

Next, the cable advancing/retracting mechanism **100** will be described in detail.

As illustrated in FIGS. **11** and **12**, the cable advancing/retracting mechanism **100** includes a lever member **110**, the casing member **120**, a cover **130**, a cam member **140**, and a cable length adjustment mechanism **200**. The cover **130** blocks an opening of the casing member **120**. The cam member **140** is turnably housed inside the casing member **120**. The cable length adjustment mechanism **200** is composed of a cable adjuster **150** and a cable adjuster moving unit **201**.

The lever member **110** includes an arm **113**, a ring portion **111**, and a stopper projection **116**. The arm **113** extends in the direction of a radius of rotation of the casing member **120**. The ring portion **111** is integrated at a base end portion of the arm **113**, and has a circular hole **112** that is provided in the center of the ring portion **111** and that is coaxial with the center of turning motion of the seat back **16**. The stopper projection **116** is provided to project in the axial direction from a side surface of the ring portion **111**. The lever member **110** is fixed to the seat cushion **17** through a distal end portion **114** of the arm **113**.

The casing member **120** includes an annular outer peripheral wall **121**, a cylindrical boss portion **123**, and a cable introduction portion **126**. The outer peripheral wall **121** covers the periphery of the cam member **140**. The boss portion **123** is provided on the inner side of the outer peripheral wall **121** via an annular recessed portion **122**. The cable introduction portion **126** projects to the outside from a part of the outer peripheral wall **121**. The cable introduction portion **126** is provided with cable guide grooves **127a** and **127b** that extend in the direction of a tangent to the annular recessed portion **122**. The cable guide groove **127a** on the outer side is formed to have a size (large groove width) that allows insertion of the

16

terminal of the exterior tube **13b** of the cable unit **13** and the terminal member **13d** attached to the terminal. The cable guide groove **127b** on the inner side is formed to have a size (small groove width) that allows insertion of only the inner cable **13a** drawn out of the terminal of the exterior tube **13b**. The cable guide groove **127a** on the outer side is provided with an exterior tube terminal fixing portion **128** for positioning and fixing of the terminal member **13d** of the exterior tube **13b**.

An abutment stepped portion **129** is provided on the inner periphery of the outer peripheral wall **121** of the casing member **120**. The abutment stepped portion **129** abuts against one end **143a** of a cam portion **143** of the cam member **140** to be discussed later when the casing member **120** is turned in the direction of the arrow Y2 of FIG. **12** to rotate the cam member **140** in the same direction in an accompanying manner.

The casing member **120** is fixed to the seat back **16** together with the cover **130** with the boss portion **123** positioned at the coupling portion **18** (see FIG. **1**) at which the seat cushion **17** and the seat back **16** are turnably coupled to each other. With the boss portion **123** of the casing member **120** fitted into the circular hole **112** of the lever member **110**, the casing member **120** is coupled coaxially with the center of turning motion of the seat back **16** so as to be turnable about the boss portion **123** with respect to the lever member **110**, and turned as the seat back **16** is tilted.

The cam member **140** is provided coaxially with the center of turning motion of the seat back **16** so as to be turnable with respect to the lever member **110** and the casing member **120**. The inner cable **13a** is wound around and drawn out of the cam member **140** in accordance with rotation to advance and retract the cable **13a** over a distance corresponding to the inclination angle of the seat back **16**. While the tilting angle of the seat back **16** is in a predetermined range (a range in which the function of the acceleration sensor **30** is used), the cam member **140** abuts against the stopper projection **116** of the lever member **110** to be discussed later to be hindered from moving when the casing member **120** is turned as the seat back **16** is tilted.

In the cam member **140**, a circular hole **142** is formed in the center of a ring portion **141**, a fan-shaped cam portion **143** is formed at the outer peripheral portion of a part of the ring portion **141** in the circumferential direction, and a cable winding groove **144** is formed in the outer peripheral surface of the cam portion **143** to extend along an arc centered about the center of turning motion of the cam member **140**. The cam member **140** is turnably fitted with the boss portion **123** of the casing member **120** to be housed in the annular recessed portion **122** of the casing member **120**.

The one end **143a** of the fan-shaped cam portion **143** in the circumferential direction abuts against the stopper projection **116** of the lever member **110**. The cam member **140** is hindered from turning in the direction of the arrow Y1 in FIG. **12** with the one end **143a** in abutment with the stopper projection **116**.

The boss portion **123** of the casing member **120** is provided with a flexible lug **124** configured to prevent the ring portion **111** of the lever member **110** and the ring portion **141** of the cam member **140** from slipping off with the ring portion **111** and the ring portion **141** fitted with the boss portion **123**. The lever member **110**, the cam member **140**, and the casing member **120** are provided with positioning holes **115**, **145**, and **125**, respectively, configured to penetrate the three members **110**, **140**, and **120** when the members are aligned with each other with the seat back **16** in the standard position.

An adjuster housing recessed portion **149** is provided in a part of the ring portion **141** of the cam member **140** in the

17

circumferential direction, adjacent to the other end **143b** of the fan-shaped cam portion **143**. The cable adjuster **150** which constitutes the cable length adjustment mechanism **200** is housed in the adjuster housing recessed portion **149**. The cable adjuster **150** adjusts the length of the cable **13a** by fixing a terminal portion of the cable **13a** on the base end (lower end) side to the cam member **140** and pulling the cable **13a** to eliminate slack in the cable **13a**. The distal end (upper end) of the cable **13a** is wound around the pulley **73** (see FIGS. 4 and 6) of the attitude control mechanism **70**.

The cable adjuster **150** includes an adjuster main body **151** which is a small piece in a generally rectangular parallelepiped shape. The adjuster main body **151** is mounted to the cam member **140** so as to be linearly slidable in the direction of a tangent to a circle centered about the center of turning motion of the cam member **140** (center of turning motion of the seat back **16**). In order to guide slide operation of the adjuster main body **151**, a C-shaped guide rail **152** is provided on the inside surface of the adjuster main body **151**. The guide rail **152** is fitted with a guide rail **146** having a T-shaped cross section and formed at the bottom of the adjuster housing recessed portion **149** of the cam member **140**. The guide rail **146** having a T-shaped cross section and the C-shaped guide rail **152** are fitted with each other utilizing elasticity of a resin material constituting the guide rails, and guide the cable adjuster **150** so as to slide in the direction of the tangent. The guide rail **146** having a T-shaped cross section may be provided on the adjuster main body **151**, and the C-shaped guide rail **152** may be provided on the cam member **140**. The adjuster main body **151** may slide linearly as inclined with respect to the direction of a tangent to a circle, or may slide linearly in a direction other than the direction of a tangent to a circle.

A cable terminal fixing portion **154** is provided on the one end side of the adjuster main body **151** in the slide direction (on the side closer to the other end **143b** of the cam portion **143**). The cable terminal fixing portion **154** houses the end block **13c** attached to the terminal of the inner cable **13a** wound in the cable winding groove **144** to fix the terminal portion of the inner cable **13a**. The cable terminal fixing portion **154** is constituted as a recessed portion, and provided at the deepest end of a cable guide groove **153** configured to house the inner cable **13a**. A portion of the inner cable **13a**, which is drawn out of the terminal portion of the exterior tube **13b**, in the vicinity of the terminal of the inner cable **13a** is wound in the cable winding groove **144** of the cam portion **143** of the cam member **140** by a maximum of about one-fourth of a turn.

The cable adjuster moving unit **201** is provided on the other end side of the adjuster main body **151** in the slide direction (on the side farther from the other end **143b** of the cam portion **143**). The cable adjuster moving unit **201** moves the cable adjuster **150** to adjust the length of the cable **13a** drawn out of the terminal portion of the exterior tube **13b**.

The cable adjuster moving unit **201** is composed of a screw receiving wall **147**, a screw insertion hole **148**, a screw hole **156**, and an adjustment screw **160**. The screw receiving wall **147** is formed at an end portion of the adjuster housing recessed portion **149** of the cam member **140**. The screw insertion hole **148** is formed to penetrate the screw receiving wall **147**. The screw hole **156** is formed in an end surface of the cable adjuster **150** in the slide direction (the other end surface of the adjuster main body **151** in the slide direction). The adjustment screw **160** is screwed into the screw hole **156** of the cable adjuster **150** with the head portion received by the screw receiving wall **147** and with the distal end side of the screw shaft portion inserted through the screw insertion hole

18

148. The cable adjuster **150** is displaced to any position in the slide direction via the adjustment screw **160** by rotating the adjustment screw **160**.

An outside surface **157** of the adjuster main body **151** of the cable adjuster **150** is formed as an arcuate surface so as to secure a large slide range of the cable adjuster **150** by avoiding interference with the outer peripheral wall **121** of the casing member **120** as much as possible when the cable adjuster **150** is slid. An insertion hole **155** is formed in the adjuster main body **151** at a position closer to the outside surface **157**, which is opposite to the guide rail **152**, to extend in the plate thickness direction. The insertion hole **155** allows insertion of a jig pin **301** (see FIG. 16) into the cable adjuster **150**.

The outer peripheral wall **121** of the casing member **120** is provided with a service window **170** with a lid. The service window **170** allows the adjustment screw **160** to be rotated using a screwdriver from the outside in an assembled state. The cover **130** is screwed to the casing member **120** to cover the opening of the casing member **120** with the cam member **140** and the ring portion **111** of the lever member **110** housed in the casing member **120**.

Next, a process for assembling the seatbelt device **10** according to the embodiment to the reclining seat **15** will be described.

As the premise for assembly of the seatbelt device **10** to the reclining seat **15**, it is necessary that the sensor housing **32** of the acceleration sensor **30** should be in an adequate attitude when assembled. Herein, the attitude of the sensor housing **32** is adjusted using the cable advancing/retracting mechanism **100** and the cable **13a**. Thus, it is necessary that the cable advancing/retracting mechanism **100** and the length of the cable **13a** should be adjusted so as to correspond to the initial position (standard position) of the seat back **16** before assembly of the seatbelt device **10**.

That is, it is necessary that the cable advancing/retracting mechanism **100** should be temporarily fixed in a predetermined state, and that the length of the cable **13a** should be adjusted. In order to temporarily fix the cable advancing/retracting mechanism **100**, as illustrated in FIG. 16, a temporarily fixing pin **300** is provided to penetrate the positioning holes **115**, **145**, and **125** formed in the lever member **110**, the cam member **140**, and the casing member **120**, respectively. This allows the temporarily fixing pin **300** to temporarily fix the lever member **110**, the cam member **140**, and the casing member **120** so as not to be relatively movable.

After that, the cable advancing/retracting mechanism **100** is attached to the reclining seat **15**, a corresponding jig, or the like with the members maintained in the temporarily fixed state, and the adjustment screw **160** of the cable adjuster moving unit **201** is adjusted to adjust the position of the cable adjuster **150**. In this event, the terminal portion of the exterior tube **13b** is fixed to the casing member **120**. Thus, the length of the cable **13a** drawn out of the terminal portion of the exterior tube **13b** may be adjusted by moving the end block **13c** of the inner cable **13a** via the cable adjuster **150**. The sensor housing **32** of the acceleration sensor **30** is adjusted to an adequate direction by adequately adjusting the length of the inner cable **13a** drawn out.

In the adjustment, first, as illustrated in FIG. 16, the temporarily fixing pin **300** is inserted into the positioning holes **115**, **145**, and **125** of the lever member **110**, the cam member **140**, and the casing member **120**, respectively, to temporarily fix the lever member **110**, the cam member **140**, and the casing member **120**.

Next, the jig pin **301** is inserted into the insertion hole **155** of the cable adjuster **150**, and the cable adjuster **150** is slid

19

with a constant load in the direction of the arrow Z to eliminate slack in the cable **13a**. At this time, the load with which the jig pin **301** is pushed is monitored by a load cell.

Next, the adjustment screw **160** is tightened in that state. The head portion of the adjustment screw **160** tightly contacts the receiving surface of the screw receiving wall **147** of the cam member **140**. When the adjustment screw **160** is further tightened, the cable adjuster **150** is pulled to reduce a force with which the jig pin **301** is pushed. When the load with which the jig pin **301** is pushed indicated by the load cell is reduced to a set load, tightening of the adjustment screw **160** is stopped. The adjustment of the length of the inner cable **13a** is thus completed.

Next, operation of the cable advancing/retracting mechanism **100** to advance and retract the inner cable **13a** will be described.

FIGS. **13** to **15** illustrate the state of the seatbelt retractor and the cable advancing/retracting mechanism at each tilting angle of the seat back. FIG. **13** illustrates a state with the seat back leaned rearward by 15° in a standard attitude. FIG. **14** illustrates a state with the seat back leaned rearward by 95°. FIG. **15** illustrates a state with the seat back leaned forward by 75°.

The cable advancing/retracting mechanism **100** allows the inner cable **13a** to be advanced and retracted by a length corresponding to the tilting angle of the seat back **16** when the seat back **16** is tilted. For example, in the case where the seat back **16** is tilted in the direction of the arrow Y1 from the reference attitude indicated in FIG. **13** to the position indicated in FIG. **14**, the one end **143a** of the cam portion **143** of the cam member **140** abuts against the stopper projection **116** of the lever member **110** to make the cam member **140** immovable. However, the casing member **120** is turned together with the seat back **16**, and thus the exterior tube **13b** of the cable **13a** is moved together with the casing member **120**. This allows the terminal of the inner cable **13a** to be drawn out of the exterior tube **13b**. Thus, the cable **13a** is subjected to draw-in operation in the direction of the arrow N1 (corresponding to wind-up operation for the cable winding groove **144** of the cam portion **143**), which is transmitted to the attitude control mechanism **70**.

In the case where the seat back **16** is returned from the position indicated in FIG. **14** to the position indicated in FIG. **13**, conversely, the casing member **120** is rotated in the opposite direction (direction of the arrow Y2) to return the exterior tube **13b** toward the terminal of the inner cable **13a**. Thus, the inner cable **13a**, which has been pulled by the torsion spring **75** of the attitude control mechanism **70**, is returned into the exterior tube **13b**. Thus, the inner cable **13a** is subjected to push-out operation in the direction of the arrow N2 (corresponding to draw-out operation for the cable winding groove **144** of the cam portion **143**), which is transmitted to the attitude control mechanism **70**.

In the case where the seat back **16** is turned in the direction of the arrow Y2 to be folded from the position indicated in FIG. **13** to the position indicated in FIG. **15**, the casing member **120** is turned together with the seat back **16**. After the abutment stepped portion **129** of the casing member **120** abuts against the one end **143a** of the cam portion **143** of the cam member **140**, the cam member **140** is also turned together with the casing member **120**. Thus, the inner cable **13a** is not subjected to draw-in operation with respect to the exterior tube **13b**. However, an occupant is not seated on the seat

20

cushion **17** in the folded state, and there is no problem if the sensor housing **32** is not maintained in a horizontal state.

The effect of the embodiment will be described below.

When the reclining angle of the seat back **16** is adjusted, the inner cable **13a** is advanced and retracted by a length corresponding to the reclining angle, and the pulley **73** of the attitude control mechanism **70** is rotated in accordance with the advancement and retraction of the inner cable **13a**. When the pulley **73** is rotated in the same direction as the tilting direction of the seat back **16**, the adjustment gear **74** is turned in the opposite direction by the same angle as the tilting angle of the pulley **73**. The turning motion of the adjustment gear **74** is transmitted to the sensor housing **32** through the pin **74c** and the slit **32h**, and the sensor housing **32** is turned in the opposite direction by the same angle as the tilting angle of the seat back **16** to keep the inertial element support surface **33** of the sensor housing **32** generally horizontal.

In this event, as discussed above, a deviation in rotational angle is caused in accordance with the rotational angle positions of the adjustment gear **74** and the sensor housing **32**, and the deviation in rotational angle is corrected with the pulley **73** rotated such that the deviation in rotational angle is compensated for by variations in radius of the cable winding groove **73b**. Thus, the inclination angle of the seat back **16** and the rotational angle of the sensor housing **32** are accurately synchronized with each other. As a result, the inertial element support surface **33** of the sensor housing **32** is always kept accurately horizontal irrespective of the reclining angle of the seat back **16**.

When acceleration in a horizontal direction that is larger than a predetermined value is applied to the acceleration sensor **30** because of a crash of the vehicle or the like, the ball **35**, which is an inertial element placed on the inertial element support surface **33**, is displaced from the neutral position. Consequently, the second sensor lever **37** is turned, and the turning motion of the second sensor lever **37** is transferred to the first sensor lever **36** to turn the first sensor lever **36**. Then, the upper lug portion **36b** is engaged with the engagement lugs **25a** of the steering wheel **25** to restrict rotation of the steering wheel **25**, which hinders the seatbelt **19** from being paid out to restrain an occupant.

Since inclination of the sensor housing **32** in the front-back direction of the vehicle is always maintained in a generally horizontal state, the acceleration sensor **30** adequately detects acceleration in each case, including a case where gentle deceleration in the vehicle advancing direction is applied and a case where a transition is made from gentle deceleration to rapid deceleration, to lock draw-out of the seatbelt **19** without causing a delay in locking the seatbelt **19**.

In the seatbelt device **10**, the cable length adjustment mechanism **200** of the cable advancing/retracting mechanism **100** is provided at the cam member **140** which actually detects the tilting angle of the seat back **16**, and adjusts the length of the inner cable **13a** drawn out of the terminal portion of the exterior tube **13b** by moving with the cable adjuster **150** pulling the terminal portion of the inner cable **13a**. Thus, the length of the inner cable **13a** may be adjusted accurately such that no slack is caused in the inner cable **13a**. Thus, the accuracy in advancing and retracting the inner cable **13a** in accordance with the reclining angle of the seat back **16** is enhanced to improve the performance of the acceleration sensor **30**. The cable adjuster **150** is disposed at the outer peripheral portion of the cam member **140**, which may make the cable advancing/retracting mechanism **100** compact in outer shape.

With the cable advancing/retracting mechanism **100**, the position of the cable adjuster **150** may be changed by a simple

21

operation of turning the adjustment screw **160**, and the length of the inner cable **13a** may be adjusted such that no slack is caused in the cable **13a**.

With the seatbelt device **10** according to the embodiment, as described above, a deviation in rotational angle caused between the adjustment gear **74** and the sensor housing **32** is compensated for by the compensation unit provided between the cable advancing/retracting mechanism **100** and the attitude control mechanism **70**. Thus, the inclination angle of the seat back **16** and the rotational angle of the sensor housing **32** may be accurately synchronized with each other. Thus, it is possible to keep the inertial element support surface **33**, which serves as the sensor reference surface, accurately horizontal even at any seat back inclination angle to improve the accuracy of the acceleration sensor **30**.

With the seatbelt device **10** according to the embodiment, in particular, fluctuations in length of the inner cable **13a** are accommodated as variations in rotation of the pulley **73** due to the profile of the cable winding groove **73b** (compensation unit) of the pulley **73** of the attitude control mechanism **70**. Thus, the present invention is easily feasible just by preparing such a pulley **73**.

According to the embodiment, even if a condition for occurrence of a deviation in rotational angle between the adjustment gear **74** and the sensor housing **32** is met with the turning axis L2 of the adjustment gear **74** and the swing axis L1 of the sensor housing **32** not on an identical line, the presence of the compensation unit (profile of the cable winding groove **73b** of the pulley **73**) eliminates the need to provide the retractor frame **21** with a dedicated attachment portion such as a bent portion, which allows the retractor frame **21** attached as inclined to the left and right seats to be provided as a common part. Thus, commonality of the retractor frame **21**, which is difficult to prepare, is achieved to contribute to a cost reduction.

The attitude control mechanism **70** further includes the adjustment gear **74** and the rotation transfer mechanism **76**. The adjustment gear **74** is turned in synchronization with rotation of the pulley **73** by an angle corresponding to the distance over which the cable **13a** is advanced or retracted by the cable advancing/retracting mechanism **100**. The rotation transfer mechanism **76** transfers rotation of the adjustment gear **74** to the sensor housing **32** to swing the sensor housing **32** in the front-back direction of the vehicle. The sensor cover **31** is provided separately from the attitude control mechanism **70**, and formed such that the turning axis L2 of the adjustment gear **74** and the swing axis L1 of the sensor housing **32** intersect each other at a predetermined angle with respect to the left-right direction of the vehicle with the swing axis L1 of the sensor housing **32** arranged in a horizontal direction with respect to the left-right direction of the vehicle. This allows the inertial element support surface **33**, which serves as the sensor reference surface, to be kept horizontal even at any inclination angle of the seat back **16**, which allows adequate detection of acceleration.

According to the embodiment, different parts for the right and left seats are provided for the sensor housing **32**, the sensor cover **31**, the pulley **73**, and so forth, and commonality is achieved for the remaining parts. Thus, commonality of constituent parts is achieved even for the seatbelt retractor which is attached in different attitudes between the right seat and the left seat.

The present invention is not limited to the embodiment discussed above, and may be modified, improved, etc. as appropriate. Besides, the material, shape, dimension, number, location, etc. of the constituent elements in the embodi-

22

ment discussed above may be determined as desired as long as the present invention is achieved, and are not limited.

For example, in the seatbelt device according to the embodiment described above, the cable winding groove **73b** of the pulley **73** of the attitude control mechanism **70** has a spline curve profile to constitute a compensation unit. However, the cable winding groove **144** of the cam member **140** of the cable advancing/retracting mechanism **100** may have a spline curve profile to constitute a compensation unit.

That is, the winding radius of the cable **13a** is set so as to be varied in accordance with the rotational angle of the cam member **140** by forming the cable winding groove **144** of the cam member **140** of the cable advancing/retracting mechanism **100** in a spline curve shape. This allows a deviation in rotational angle between the adjustment gear **74** and the sensor housing **32** to be compensated for. In this case, the cable winding groove **73b** of the pulley **73** of the attitude control mechanism **70** has a perfect circle profile rather than a spline curve profile.

In another embodiment, for the compensation unit configured to compensate for a deviation in rotational angle between the adjustment gear **74** and the sensor housing **32**, the same effect is achieved if a support shaft for the pulley **73** of the attitude control mechanism **70**, that is, the support shaft **71c** of the first pulley case **71** which supports the pulley **73** in the embodiment, has a spline curve profile.

In the embodiment described above, the adjustment gear **74** is meshed with the gear **73a** of the pulley **73** of the attitude control mechanism **70** so that rotation of the adjustment gear **74**, which serves as a rotary member, is transferred to the sensor housing **32** through a combination of the pin **74c** and the slit **32h**. However, the pulley **73** itself may constitute a rotary member.

That is, the pulley **73** of the attitude control mechanism **70** may be rotated in the direction opposite to the rotational direction of the seat back **16** if the direction of winding the inner cable **13a** around the pulley **73** is set to the opposite to that in the embodiment described above. Thus, the sensor housing **32** may be turned in the direction opposite to the rotational direction of the seat back **16** by providing the pulley **73** with a pin to be engaged with the slit **32h** of the sensor housing **32**.

Also in this case, the rotational track surface of the pulley **73** and the rotational track surface of the sensor housing **32** are non-parallel with each other, and a compensation unit is provided between the cable advancing/retracting mechanism **100** and the attitude control mechanism **70**. The compensation unit is configured to compensate for a deviation in rotational angle caused by such non-parallelism between the two rotational track surfaces when rotation is transmitted from the pulley **73** to the sensor housing **32**.

Besides, the cable advancing/retracting mechanism **100** may be of a rack and pinion type, for example.

In the embodiment described above, the adjustment screw **160** is used in the cable adjuster moving unit **201** of the cable advancing/retracting mechanism **100**. However, the cable adjuster moving unit **201** may include a spring configured to urge the cable adjuster **150** in the direction of drawing the inner cable **13a** out of the terminal portion of the exterior tube **13b**. In the case where a compression coil spring is used, for example, the compression coil spring may be interposed between the cable adjuster **150** and the other end **143b** of the cam portion **143** to urge the cable adjuster **150** in the direction of moving away from the other end **143b** of the cam portion **143**. When such a spring is used, the cable adjuster **150** may be moved by the urging force of the spring to adjust the length of the cable **13a** such that no slack is caused in the cable **13a**.

23

The present invention is based on Japanese Patent Application No. 2011-248981 filed on Nov. 14, 2011, Japanese Patent Application No. 2011-248982 filed on Nov. 14, 2011, and Japanese Patent Application No. 2011-273694 filed on Dec. 14, 2011, the contents of which are incorporated herein by reference.

What is claimed is:

1. A seatbelt device for a reclining seat of a vehicle, the seatbelt device comprising:

a seatbelt retractor attached to a seat back of the reclining seat and configured to wind up a seatbelt when necessary; and

a cable advancing/retracting mechanism disposed at a coupling portion at which the seat back and a seat cushion of the reclining seat are coupled to each other and configured to detect an inclination angle of the seat back when the seat back is tilted in a front-back direction of a vehicle, the cable advancing/retracting mechanism including a cable configured to transmit the inclination angle to the seatbelt retractor and advance and retract in a longitudinal direction of the cable over a distance corresponding to the inclination angle of the seat back, the seatbelt retractor including:

a retractor frame fixed to the seat back as inclined in a left-right direction of the vehicle with respect to a line extending in an up-down direction at a center of the seat back in the left-right direction;

a spindle supported by the retractor frame and configured to wind up the seatbelt;

an acceleration sensor attached to the retractor frame to detect acceleration in the front-back direction of the vehicle;

a lock mechanism configured to lock draw-out operation for the seatbelt in accordance with the acceleration in the front-back direction of the vehicle detected by the acceleration sensor; and

an attitude control mechanism configured to keep a sensor reference surface of the acceleration sensor horizontal,

the acceleration sensor including:

a sensor cover fixed to the retractor frame;

an inertial element configured to be moved in the front-back direction of the vehicle when acceleration that is equal to or more than a predetermined value is applied in the front-back direction of the vehicle;

a sensor housing supported on the sensor cover and having a swing axis extending along the left-right direction of the vehicle and an inertial element support surface on which the inertial element is placed; and

an actuation member configured to actuate the lock mechanism to lock the draw-out operation in conjunction with movement of the inertial element in the front-back direction of the vehicle, and

the attitude control mechanism including:

a rotary member configured to be turned by an angle corresponding to a distance over which the cable is advanced or retracted by the cable advancing/retracting mechanism; and

a rotation transfer mechanism configured to transfer rotation of the rotary member to the sensor housing to swing the sensor housing in the front-back direction of the vehicle, wherein

a turning axis of the rotary member and the swing axis of the sensor housing intersect each other at a predetermined angle with respect to the left-right direction of the vehicle with the swing axis of the sensor housing

24

arranged in a horizontal direction with respect to the left-right direction of the vehicle,

the inertial element support surface of the sensor housing is kept horizontal by swing motion of the sensor housing in the front-back direction of the vehicle even if the seat back is tilted in the front-back direction of the vehicle, a rotational track surface of the rotary member and a rotational track surface of the sensor housing are non-parallel with each other, and

a compensation unit is provided between the cable advancing/retracting mechanism and the attitude control mechanism, the compensation unit being configured to compensate for a deviation in rotational angle caused by such non-parallelism between the two rotational track surfaces when the rotation transfer mechanism transmits rotation from the rotary member to the sensor housing.

2. The seatbelt device according to claim 1, wherein the attitude control mechanism includes a pulley configured to convert advancing and retracting motion of the cable into rotational motion to transmit rotation to the rotary member, and a winding radius of the cable is set so as to be varied in accordance with a rotational angle of the pulley by forming a cable winding portion of the pulley in a spline curve shape, and

the compensation unit is constituted by the cable winding portion of the pulley formed in the spline curve shape.

3. The seatbelt device according to claim 1, wherein the cable advancing/retracting mechanism includes a cam member configured to allow the cable to be wound and pulled out in accordance with rotation to advance and retract the cable over a distance corresponding to the inclination angle of the seat back, and a winding radius of the cable is set so as to be varied in accordance with a rotational angle of the cam member by forming a cable winding portion of the cam member in a spline curve shape, and

the compensation unit is constituted by the cable winding portion of the cam member formed in the spline curve shape.

4. The seatbelt device according to claim 1, wherein the rotation transfer mechanism includes a pin and a slit provided on the rotary member and in the sensor housing, respectively, and disposed at positions away from the swing axis and the turning axis in a radial direction to be engaged with each other.

5. A seatbelt device for a reclining seat of a vehicle, the seatbelt device comprising:

a seatbelt retractor attached to a seat back of the reclining seat and configured to wind up a seatbelt when necessary; and

a cable advancing/retracting mechanism disposed at a coupling portion at which the seat back and a seat cushion of the reclining seat are coupled to each other and configured to detect an inclination angle of the seat back when the seat back is tilted in a front-back direction of a vehicle, the cable advancing/retracting mechanism including a cable configured to transmit the inclination angle to the seatbelt retractor and advance and retract in a longitudinal direction of the cable over a distance corresponding to the inclination angle of the seat back, the seatbelt retractor including:

a retractor frame fixed to the seat back as inclined in a left-right direction of the vehicle with respect to a line extending in an up-down direction at a center of the seat back in the left-right direction;

a spindle supported by the retractor frame and configured to wind up the seatbelt;

25

an acceleration sensor attached to the retractor frame to detect acceleration in the front-back direction of the vehicle;

a lock mechanism configured to lock draw-out operation for the seatbelt in accordance with the acceleration in the front-back direction of the vehicle detected by the acceleration sensor; and

an attitude control mechanism configured to keep a sensor reference surface of the acceleration sensor horizontal, and

the acceleration sensor including:

- a sensor cover fixed to the retractor frame;
- an inertial element configured to be moved in the front-back direction of the vehicle when acceleration that is equal to or more than a predetermined value is applied in the front-back direction of the vehicle;
- a sensor housing supported on the sensor cover and having a swing axis extending along the left-right direction of the vehicle and an inertial element support surface on which the inertial element is placed; and
- an actuation member configured to actuate the lock mechanism to lock the draw-out operation in conjunction with movement of the inertial element in the front-back direction of the vehicle, wherein

the attitude control mechanism includes a pulley configured to convert advancing and retracting motion of the cable of the cable advancing/retracting mechanism into rotational motion, and a rotational track surface of the pulley and a rotational track surface of the sensor housing are non-parallel with each other, and

a compensation unit is provided between the cable advancing/retracting mechanism and the attitude control mechanism, the compensation unit being configured to compensate for a deviation in rotational angle caused by such non-parallelism between the two rotational track surfaces when rotation is transmitted from the pulley to the sensor housing.

6. The seatbelt device according to claim 5, wherein a winding radius of the cable is set so as to be varied in accordance with a rotational angle of the pulley by forming a cable winding portion of the pulley in a spline curve shape, and

the compensation unit is constituted by the cable winding portion of the pulley formed in the spline curve shape.

7. The seatbelt device according to claim 5, wherein the cable advancing/retracting mechanism includes a cam member configured to allow the cable to be wound and pulled out in accordance with rotation to advance and retract the cable over a distance corresponding to the inclination angle of the seat back, and a winding radius of the cable is set so as to be varied in accordance with a rotational angle of the cam member by forming a cable winding portion of the cam member in a spline curve shape, and

the compensation unit is constituted by the cable winding portion of the cam member formed in the spline curve shape.

8. The seatbelt device according to claim 5, wherein the attitude control mechanism further includes

- a rotary member configured to be turned by an angle corresponding to a distance over which the cable is advanced or retracted by the cable advancing/retracting mechanism in synchronization with rotation of the pulley, and

26

a rotation transfer mechanism configured to transfer rotation of the rotary member to the sensor housing to swing the sensor housing in the front-back direction of the vehicle,

the sensor cover is provided separately from the attitude control mechanism, and

the sensor cover is formed such that a turning axis of the rotary member and the swing axis of the sensor housing intersect each other at a predetermined angle with respect to the left-right direction of the vehicle with the swing axis of the sensor housing arranged in a horizontal direction with respect to the left-right direction of the vehicle.

9. The seatbelt device according to claim 8, wherein the rotation transfer mechanism includes a pin and a slit provided on the rotary member and in the sensor housing, respectively, and disposed at positions away from the swing axis and the turning axis in a radial direction to be engaged with each other.

10. The seatbelt device according to claim 5, wherein the cable advancing/retracting mechanism includes

- a lever member fixed to the seat cushion,
- a casing member disposed coaxially with a center of turning motion of the seat back so as to be turnable with respect to the lever member, the casing member being fixed to the seat back to be turned as the seat back is tilted, and
- a cam member provided coaxially with the center of turning motion of the seat back so as to be turnable with respect to the lever member and the casing member, the cam member being hindered from moving by the lever member when the casing member is turned as the seat back is tilted while the inclination angle of the seat back is in a predetermined range,

the casing member includes an exterior tube terminal fixing portion for fixation of a terminal portion of an exterior tube configured to slidably hold the cable,

the cam member includes a cable winding groove which is formed along an outer peripheral surface of the cam member and in which the cable drawn out of the terminal portion of the exterior tube is wound, and

the cam member is provided with a cable length adjustment mechanism including a cable adjuster and a cable adjuster moving unit, the cable adjuster including a cable terminal fixing portion for fixation of the terminal portion of the cable wound in the cable winding groove and mounted so as to be linearly slidable at an outer peripheral portion of the cam member, and the cable adjuster moving unit being configured to slide the cable adjuster to adjust a length of the cable drawn out of the terminal portion of the exterior tube.

11. The seatbelt device according to claim 10, wherein the cable adjuster moving unit includes

- a screw receiving wall formed on the cam member,
- a screw insertion hole formed to penetrate the screw receiving wall,
- a screw hole formed in an end surface of the cable adjuster in a slide direction, and
- an adjustment screw screwed into the screw hole of the cable adjuster with a head portion received by the screw receiving wall and with a distal end side of a screw shaft portion inserted through the screw insertion hole, and

the cable adjuster is displaced via the adjustment screw by rotating the adjustment screw.

27

12. The seatbelt device according to claim 10, wherein the cable adjuster moving unit includes a spring configured to urge the cable adjuster in a direction of drawing the cable out of the terminal portion of the exterior tube.
13. The seatbelt device according to claim 10, wherein the lever member, the casing member, and the cam member are provided with respective positioning holes configured to penetrate the three members when the members are aligned with each other.
14. The seatbelt device according to claim 10, wherein the cable adjuster is mounted at the outer peripheral portion of the cam member so as to be slidable in a direction of a tangent to a circle centered about the center of turning motion of the seat back.
15. A seatbelt device for a reclining seat of a vehicle, the seatbelt device comprising:
- a seatbelt retractor attached to a seat back of the reclining seat and configured to wind up a seatbelt when necessary; and
 - a cable advancing/retracting mechanism including a cable configured to transmit an inclination angle between the seat back and seat cushion to the seatbelt retractor and to advance and retract the cable over a distance corresponding to the inclination angle of the seat back,
 - the seatbelt retractor including an acceleration sensor attached to a retractor frame to detect acceleration in a front-back direction of the vehicle, a lock mechanism configured to lock draw-out operation for the seatbelt in accordance with the acceleration in the front-back direction of the vehicle detected by the acceleration sensor, and an attitude control mechanism configured to keep a sensor reference surface of the acceleration sensor horizontal, the acceleration sensor including an inertial element configured to be moved in the front-back direction of the vehicle when acceleration that is equal to or more than a predetermined value is applied in the front-back

28

- direction of the vehicle, the attitude control mechanism including a rotary member configured to be turned by an angle corresponding to a distance over which the cable is advanced or retracted; and
- a compensation unit provided between the cable advancing/retracting mechanism and the attitude control mechanism, the compensation unit being configured to compensate for a deviation in rotational angle caused by non-parallelism between a rotational axis of the rotary member and a rotational axis of the acceleration sensor, the rotational axis of the acceleration sensor permitting rotation in the front-back direction of the vehicle;
- wherein the rotary member is a pulley, the pulley defining a cable winding portion that receives the cable, the cable winding portion defining a non-constant radius of curvature which constitutes the compensation unit.
16. The seatbelt device according to claim 15, wherein the pulley is coupled to the cable such that the pulley is rotated about the rotational axis of the pulley in an amount corresponding to the distance over which the cable is advanced or retracted.
17. The seatbelt device according to claim 16, wherein the pulley defines a cable winding portion that receives the cable, the cable winding portion defining a spline curve shape which constitutes the compensation unit.
18. The seatbelt device according to claim 15, further comprising a rotation transfer mechanism coupled to the rotary member so as to transfer rotation in the front-back direction of the vehicle to the acceleration sensor, the rotary transfer member including a rotary part coupled to the rotary member and a sensor part coupled to the acceleration sensor, the rotary part being moveable relative to the sensor part.
19. The seatbelt device according to claim 18, wherein the rotary part and the sensor part are one of a pin and a slit.
